DRUG NAME: Abiraterone

SYNONYM(S): abiraterone acetate

COMMON TRADE NAME(S): ZYTIGA®

CLASSIFICATION: endocrine anti-hormone

Special pediatric considerations are noted when applicable, otherwise adult provisions apply.

MECHANISM OF ACTION:

Abiraterone acetate is converted, in vivo, to abiraterone, which selectively inhibits the CYP17 enzyme in testicular, adrenal and prostate tumour tissues. CYP17 enzyme inhibition reduces the conversion of pregnenolone and progesterone into testosterone precursors, DHEA and androstenedione. When used in addition to androgen deprivation therapies (luteinizing hormone releasing hormone [LHRH] agonists or orchiectomy), abiraterone further decreases androgen production to below castrate levels.\(^1\,^2\)

Elderly: no clinically significant difference

Adapted from standard reference\(^1\) unless specified otherwise.

USES:

**Primary uses:**
- *Prostate cancer*\(^1\)

*Health Canada approved indication

**Other uses:**

SPECIAL PRECAUTIONS:

**Contraindications:**
- women who are or may become pregnant\(^1\)

BC Cancer Agency Cancer Drug Manual© Page 1 of 5

Revised: 1 August 2017
Abiraterone

**Caution:**

Use caution in patients with:
- **mineralocorticoid excess**; see paragraph following Side Effects table
- **hypokalemia**; see paragraph following Side Effects table
- **cardiovascular disease** (e.g. uncontrolled hypertension, myocardial infarction, arterial thrombosis, unstable angina or reduced left ventricular ejection fraction, LVEF < 50%)
- **severe hepatic disease**; see paragraph following Side Effects table

**Carcinogenicity:** In animal studies, abiraterone was not carcinogenic in mice or female rats; however increased incidence of interstitial cell neoplasms in the testes of male rats were reported (clinical significance is unknown as this finding in male rats is believed related to pharmacological action of the drug).

**Mutagenicity:** Not mutagenic in Ames test and mammalian in vitro mutation test.

**Fertility:** Abiraterone reduced fertility in both male and female rats, although this was completely reversible 4-16 weeks after abiraterone was stopped. Reduced sperm counts, sperm motility, altered sperm morphology, and fertility were reported in males. Treated females experienced increased incidence of irregular or extended estrous cycles and pre-implantation loss. Untreated females mated with treated males experienced reduced corpora lutea, implantants, and live embryos, as well as increased pre-implantation loss.

**Pregnancy:** FDA Pregnancy Category X. Studies in animals have shown fetal abnormalities and the risk of the use of the drug in pregnant women clearly outweighs any possible benefit. The drug is contraindicated in women who are or may become pregnant. Avoid drugs that may interact with oral contraceptives.

In developmental studies in rats, abiraterone did not have teratogenic potential, but it did cause developmental toxicity throughout the period of organogenesis, including embryo-fetal lethality, fetal developmental delay, urogenital effects, and decreased fetal weight. Maternal use of abiraterone is expected to produce changes in hormone levels that could affect the development of the human fetus.

It is not known if abiraterone or its metabolites are present in semen. It is recommended that male patients taking abiraterone use a condom during sexual activity with a pregnant woman OR a condom plus another effective birth control method during sexual activity with a woman of child-bearing potential for the duration of treatment and for one week after the last dose.

**Breastfeeding** is not recommended due to the potential secretion into breast milk.

**SIDE EFFECTS:**

The table includes adverse events that presented during drug treatment but may not necessarily have a causal relationship with the drug. Because clinical trials are conducted under very specific conditions, the adverse event rates observed may not reflect the rates observed in clinical practice. Adverse events are generally included if they were reported in more than 1% of patients in the product monograph or pivotal trials, and/or determined to be clinically important. When placebo-controlled trials are available, adverse events are included if the incidence is >5% higher in the treatment group.

**hypertension** (9-22%, severe 1-4%); see paragraph following Side Effect table |

Adapted from standard reference<sup>1</sup> unless specified otherwise.

The **mineralocorticoid effects** of abiraterone can occur due to the compensatory increase in ACTH. Therefore, pre-existing cardiovascular disease can be worsened with increased **hypertension, hypokalemia and fluid retention**. Concomitant use of corticosteroids suppresses ACTH drive which reduces the incidence and severity of these reactions. If corticosteroids are withdrawn, monitor for adrenocortical insufficiency. If abiraterone is continued after corticosteroids are withdrawn, monitor for symptoms of mineralocorticoid excess.<sup>2</sup> Avoid choosing spironolactone as a potassium-sparing diuretic because it may stimulate the androgen receptor and cause disease progression.<sup>1</sup>

**Hepatotoxicity** with marked increases in **liver enzymes** has been reported with abiraterone, with liver function abnormalities typically occurring during the first three months after starting treatment. Patients with elevated baseline ALT/AST may be more likely to experience liver function test elevations than normal baseline values. Regular monitoring of serum transaminases and bilirubin is recommended. Suggest treatment interruption for elevated ALT/AST (>5 X ULN) or bilirubin (>3 X ULN); continue treatment at a reduced dose after tests return to baseline. Patients developing severe hepatotoxicity (AST/ALT 20 X ULN) during treatment should not be retreated with abiraterone.<sup>3</sup>

Abiraterone is a substrate of CYP 3A4 in vitro. Strong inhibitors or inducers of CYP 3A4 may result in an increase or decrease in the plasma concentration of abiraterone.

Abiraterone is a strong inhibitor of CYP 1A2, CYP 2D6, and CYP 2C8 in vitro and may also be a moderate inhibitor of CYP 2C9, CYP 2C19 and CYP 3A4/5. Plasma concentration of substrates of these enzymes may be increased when taken with abiraterone.

Abiraterone acetate is an inhibitor of P-glycoprotein (P-gp) in vitro. Plasma concentration of substrates of P-gp may be increased when taken with abiraterone.

SUPPLY AND STORAGE:

**Oral:** Janssen Inc. supplies abiraterone as uncoated 250 mg tablets and film-coated 500 mg tablets. Tablets contain lactose. Store at room temperature.

DOSAGE GUIDELINES:

Refer to protocol by which patient is being treated. Numerous dosing schedules exist and depend on disease, response, and concomitant therapy. Guidelines for dosing also include consideration of absolute neutrophil count (ANC). Dosage may be reduced, delayed or discontinued in patients with bone marrow depression due to cytotoxic/radiation therapy or with other toxicities.

**Adults:**

**Oral:**

1 g once daily

Administer on an empty stomach (one hour before or two hours after food).

**Dosage in renal failure:**

no adjustment required

**Dosage in hepatic failure:**

For baseline or pre-existing:
- mild impairment - no adjustment required
- moderate impairment (Child-Pugh Class B) - consider reduced starting dose of 250 mg
- severe impairment (Child-Pugh Class C) - avoid use

**Dosage in dialysis:**

no adjustment required

**Children:**

no information found
